

Abstract of the Disclosure:

A method for equalizing and decoding an error-protected data signal transmitted via a radio channel is described.

According to the method, an equalized data signal is

5 calculated at the receiving end in a demodulator with a first channel estimator. The equalized data signal is decoded by a decoder to determine a decoded output signal. The equalized data signal is transmitted to a second channel estimator, which repeatedly detects second channel parameters of the

10 radio channel. The parameters are transmitted to the decoder which uses them as calculation parameters during decoding.
